## 1 Introduction

Given the opportunity to review the design document and related source code of the Vite/ETH token contract, we outline in the report our systematic method to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistency between smart contract code and the documentation, and provide additional suggestions or recommendations for improvement. Our results show that the given version of the smart contract can be further improved due to the presence of some issues related to ERC20-compliance, security, or performance. This document outlines our audit results.

### 1.1 About Vite/ETH

Vite is a lightning-fast public blockchain where transactions incur zero fees. It is arguably one of DAG-based smart contract platforms with the flagship DApp ViteX, a trustless DEX deployed on the Vite chain. ViteX adopts the most cutting-edge decentralized exchange technology by implementing on-chain order matching, settlement, mining, and dividends distribution through smart-contracts on Vite chain. It is proposed and designed with the vision that many blockchains will grow to serve different needs and Vite aims to bridge current blockchains in a decentralized way.

The audited Vite token contract follows the ERC20 standard and is deployed at the Ethereum blockchain. The basic information is as follows:

Table 1.1: Basic Information of Vite Token

In the following, we show the audited contract code deployed at the Ethereum blockchain with the following address:

https://etherscan.io/address/0xadd5e881984783dd432f80381fb52f45b53f3e70#code

#### 1.2 About PeckShield

PeckShield Inc. [6] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

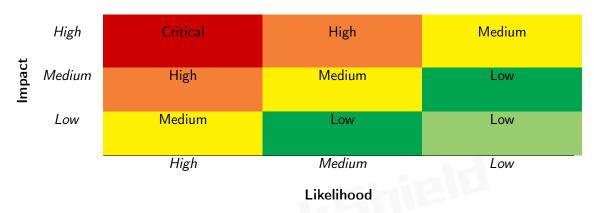

Table 1.2: Vulnerability Severity Classification

### 1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [5]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk;

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

We perform the audit according to the following procedures:

- <u>Basic Coding Bugs</u>: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>ERC20 Compliance Checks</u>: We then manually check whether the implementation logic of the audited smart contract(s) follows the standard ERC20 specification and other best practices.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

Table 1.3: The Full List of Check Items

Category	Check Item
	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows
	Reentrancy
	Money-Giving Bug
	Blackhole
	Unauthorized Self-Destruct
Basic Coding Bugs	Revert DoS
Dasic Couling Dugs	Unchecked External Call
	Gasless Send
	Send Instead of Transfer
	Costly Loop
	(Unsafe) Use of Untrusted Libraries
	(Unsafe) Use of Predictable Variables
	Transaction Ordering Dependence
	Deprecated Uses
	Approve / TransferFrom Race Condition
ERC20 Compliance Checks	Compliance Checks (Section 3)
	Avoiding Use of Variadic Byte Array
	Using Fixed Compiler Version
Additional Recommendations	Making Visibility Level Explicit
	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

To evaluate the risk, we go through a list of check items and each would be labeled with a severity

category. For one check item, if our tool does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

#### 1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

# 2 | Findings

#### 2.1 Summary

Here is a summary of our findings after analyzing the Vite/ETH token contract. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place ERC20-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings
Critical	0
High	0
Medium	1
Low	1
Informational	0
Total	2

Moreover, we explicitly evaluate whether the given contracts follow the standard ERC20 specification and other known best practices, and validate its compatibility with other similar ERC20 tokens and current DeFi protocols. The detailed ERC20 compliance checks are reported in Section 3. After that, we examine a few identified issues of varying severities that need to be brought up and paid more attention to. (The findings are categorized in the above table.) Additional information can be found in the next subsection, and the detailed discussions are in Section 4.

#### 2.2 Key Findings

Overall, no ERC20 compliance issue was found, although the smart contract implementation can be improved due to the existence of 1 medium-severity and 1 low-severity issues. Our detailed checklist can be found in Section 3.

Table 2.1: Key Vite Token Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Redundant State/Code Removal	Coding Practices	Confirmed
PVE-002	Medium	Trust Issue Of Admin Roles	Business Logic	Confirmed

Besides recommending specific countermeasures to mitigate these issues, we also emphasize that it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms need to kick in at the very moment when the contracts are being deployed in mainnet. Please refer to Section 3 for our detailed compliance checks and Section 4 for elaboration of reported issues.

# 3 | ERC20 Compliance Checks

The ERC20 specification defines a list of API functions (and relevant events) that each token contract is expected to implement (and emit). The failure to meet these requirements means the token contract cannot be considered to be ERC20-compliant. Naturally, as the first step of our audit, we examine the list of API functions defined by the ERC20 specification and validate whether there exist any inconsistency or incompatibility in the implementation or the inherent business logic of the audited contract(s).

Table 3.1: Basic View-Only Functions Defined in The ERC20 Specification

Item	Description	Status
name()	Is declared as a public view function	✓
name()	Returns a string, for example "Tether USD"	✓
symbol()	Is declared as a public view function	
Syllibol()	Returns the symbol by which the token contract should be known, for	✓
	example "USDT". It is usually 3 or 4 characters in length	
decimals()	Is declared as a public view function	✓
decimais()	Returns decimals, which refers to how divisible a token can be, from 0	✓
	(not at all divisible) to 18 (pretty much continuous) and even higher if	
	required	
totalSupply()  Is declared as a public view function  Determine the property of total property of tota		✓
total Supply()	Returns the number of total supplied tokens, including the total minted	✓
	tokens (minus the total burned tokens) ever since the deployment	
balanceOf()	Is declared as a public view function	✓
balanceO1()	Anyone can query any address' balance, as all data on the blockchain is	✓
	public	
allowance()	Is declared as a public view function	✓
anowance()	Returns the amount which the spender is still allowed to withdraw from	✓
	the owner	

Our analysis shows that there is no ERC20 inconsistency or incompatibility issue found in the audited Vite/ETH token contract. In the surrounding two tables, we outline the respective list of basic view-only functions (Table 3.1) and key state-changing functions (Table 3.2) according to the

widely-adopted ERC20 specification.

Table 3.2: Key State-Changing Functions Defined in The ERC20 Specification

Item	Description	Status
	Is declared as a public function	✓
	Returns a boolean value which accurately reflects the token transfer status	✓
two mefor()	Reverts if the caller does not have enough tokens to spend	✓
transfer()	Allows zero amount transfers	✓
	Emits Transfer() event when tokens are transferred successfully (include 0	✓
	amount transfers)	
	Reverts while transferring to zero address	✓
	Is declared as a public function	✓
	Returns a boolean value which accurately reflects the token transfer status	✓
	Reverts if the spender does not have enough token allowances to spend	✓
	Updates the spender's token allowances when tokens are transferred suc-	✓
transferFrom()	cessfully	
	Reverts if the from address does not have enough tokens to spend	✓
	Allows zero amount transfers	✓
	Emits Transfer() event when tokens are transferred successfully (include 0	✓
	amount transfers)	
	Reverts while transferring from zero address	✓
	Reverts while transferring to zero address	✓
	Is declared as a public function	✓
approve()	Returns a boolean value which accurately reflects the token approval status	✓
approve()	Emits Approval() event when tokens are approved successfully	✓
	Reverts while approving to zero address	✓
Transfer() event	Is emitted when tokens are transferred, including zero value transfers	✓
riansier() event	Is emitted with the from address set to $address(0x0)$ when new tokens	✓
	are generated	
Approval() event	Is emitted on any successful call to approve()	✓

In addition, we perform a further examination on certain features that are permitted by the ERC20 specification or even further extended in follow-up refinements and enhancements, but not required for implementation. These features are generally helpful, but may also impact or bring certain incompatibility with current DeFi protocols. Therefore, we consider it is important to highlight them as well. This list is shown in Table 3.3.

Table 3.3: Additional Opt-in Features Examined in Our Audit

Feature	Description	Opt-in
Deflationary	Part of the tokens are burned or transferred as fee while on trans-	_
	fer()/transferFrom() calls	
Rebasing	The balanceOf() function returns a re-based balance instead of the actual	_
	stored amount of tokens owned by the specific address	
Pausable	The token contract allows the owner or privileged users to pause the token	✓
	transfers and other operations	
Blacklistable	The token contract allows the owner or privileged users to blacklist a	_
	specific address such that token transfers and other operations related to	
	that address are prohibited	
Mintable	The token contract allows the owner or privileged users to mint tokens to	✓
	a specific address	
Burnable	The token contract allows the owner or privileged users to burn tokens of	✓
	a specific address	

## 4 Detailed Results

#### 4.1 Redundant State/Code Removal

• ID: PVE-001

Severity: Low

• Likelihood: Low

• Impact: Low

• Target: Multiple Contracts

• Category: Coding Practices [4]

• CWE subcategory: CWE-563 [2]

#### Description

The VITE/ETH token contract makes good use of a number of reference contracts, such as ERC20, AccessControl, Pausable, and Ownable, to facilitate its code implementation and organization. For example, the ERC20PresetMinterPauser smart contract has so far imported at least four reference contracts. However, we observe the inclusion of certain unused code or the presence of unnecessary redundancies that can be safely removed.

For example, if we examine closely the erc20\_decimals and erc20\_units private state variables defined in ViteToken, these two variables are not used anywhere. To elaborate, we show below the ViteToken contract. Note these two private state variables are defined at lines 1612 and 1613, respectively.

```
1611
     contract ViteToken is ERC20PresetMinterPauser {
1612
          uint256 private erc20 decimals = 18;
1613
          uint256 private erc20 units = 10**erc20 decimals;
1614
          constructor() public ERC20PresetMinterPauser("Vite", "VITE") {}
1615
1616
1617
1618
           * @dev See {ERC20-_beforeTokenTransfer}.
1619
1620
          function _ beforeTokenTransfer(
1621
              address from,
1622
              address to.
1623
              uint256 amount
```

Listing 4.1: The ViteToken Contract

Moreover, there is another abstract contract Ownable that is defined, but not used either. We also suggest to remove this Ownable contract.

**Recommendation** Consider the removal of the redundant code with a simplified, consistent implementation.

**Status** This issue has been confirmed.

#### 4.2 Trust Issue Of Admin Roles

• ID: PVE-002

• Severity: Medium

Likelihood: Low

Impact: High

• Target: CoinToken

• Category: Security Features [3]

• CWE subcategory: CWE-287 [1]

#### Description

In the Vite/ETH token contract, the admin account plays a critical role in governing and regulating the entire operation and maintenance (e.g., role assignment). Specifically, it can assign the MINTER\_ROLE to an account to have the privilege to mint any given amount. Also, it can assign PAUSER\_ROLE to another account to pause the current token contract.

```
1552
1553
           * @dev Creates 'amount' new tokens for 'to'.
1554
1555
           * See {ERC20-_mint}.
1556
1557
           * Requirements:
1558
1559
           * - the caller must have the 'MINTER_ROLE'.
1560
           */
1561
          function mint(address to, uint256 amount) public virtual {
1562
              require(hasRole(MINTER ROLE, msgSender()), "ERC20PresetMinterPauser: must have
                  minter role to mint");
1563
              mint(to, amount);
1564
          }
1565
1566
1567
           * @dev Pauses all token transfers
```

```
1568
1569
           * See {ERC20Pausable} and {Pausable-_pause}.
1570
1571
            Requirements:
1572
1573
               the caller must have the 'PAUSER_ROLE'.
1574
1575
          function pause() public virtual {
1576
              require(hasRole(PAUSER ROLE, msgSender()), "ERC20PresetMinterPauser: must have
                  pauser role to pause");
1577
              _pause();
1578
```

Listing 4.2: ERC20PresetMinterPauser::mint() And ERC20PresetMinterPauser::pause()

To elaborate, we show above a privileged mint() function. This function allows for any account with MINTER\_ROLE to mint more tokens into circulation without being capped. We understand the need of the privileged functions for contract operation and maintenance, but at the same time the extra power to the owner may also be a counter-party risk to the contract users. Therefore, we list this concern as an issue here from the audit perspective and highly recommend making these privileges explicit or raising necessary awareness among contract users.

**Recommendation** Make the list of extra privileges granted to admin explicit to Vite Token users.

Status This issue has been confirmed.

# 5 Conclusion

In this security audit, we have examined the design and implementation of the Vite/ETH token contract. During our audit, we first checked all respects related to the compatibility of the ERC20 specification and other known ERC20 pitfalls/vulnerabilities. We then proceeded to examine other areas such as coding practices and business logics. Overall, although no critical vulnerabilities were discovered, we identified two issues of varying severities that were promptly confirmed and fixed by the team. In the meantime, as disclaimed in Section 1.4, we appreciate any constructive feedbacks or suggestions about our findings, procedures, audit scope, etc.
